**Abstract**

**Introduction:** Tobacco Chewing is most prevailing habit in India especially In South East Asia and Western U.P Which could result into most common premalignant condition that is Oral Submucous fibrosis. Digital Lateral Cephalogram provides better visualization and to analyse the changes in morphometric and morphology of soft palate.

**Aim & objective:** The aim of the present study is to assess the morphological and morphometric variations of

soft palate in Oral sub mucous fibrosis (OSMF) with respect to age and gender and to assess inter group comparison of the morphology of soft palate variations in individuals with or without oral submucous fibrosis (OSMF), by digital lateral cephalogram.

**Materials and methodology:** A total of 100 subjects of both the gender, were randomly divided in two group such as Group I(study) consist of total fifty Subjects who are clinically diagnosed OSMF and Group II(control) consist of 50 Subjects having history of habit with no

mucosal changes within the age group of 18-45 year. Later the morphology and morphometric changes of Soft Palate was evaluated using Digital Lateral cephalogram followed by statistical analysis.

**Results:** In Group I (Study) Type 1(Leaf) shapes commonly noticed. In Group II (control) predominantly Type 2 (Rat-tail) shape was found. Anteroposterior dimension between the groups with mean length of 26.96 with Std. Deviation 5.083 in group I (study group) and 28.87mean length with Std. Deviation 3.187 in Group II (control group) were found to be statistically significant. SI width in Group I (study group) 7.96 with Std. Deviation 0.179 and in Group II (control group) 7.98 with Std. Deviation 0.202 had been found to be non-significant. Other than this Two new shapes Triangular and beak shapes were Recorded in the study.

**Conclusion:** Digital Lateral Cephalogram proves a better imaging modality then conventional radiographs and advanced imaging techniques like CT, MRI as it has low cost, less time consuming, low radiation and can be done as often as required in assessment of shapes of velum in different conditions.

**Keywords:** Oral Submucous Fibrosis, Soft palate, Digital Lateral cephalogram.

### **Introduction**

In India the common form used is smokeless form of tobacco and frequently used products are Tambakoo, khaini, gutkha, betel leaf with tobacco and results in OSMF and it is accepted, having highest malignant potential than any other oral premalignant lesions.<sup>1</sup>

OSMF is a harmful disorder of oral cavity. It is having multifactorial Etiology factor such as areca nut, capsaicin, deficiencies of iron, zinc, and necessary vitamins, autoimmune disease and relation with specific human leukocyte antigen (HLA) antigen.

OSMF is a persistent impairing ailment leads to a fibrosis that not only involves oral cavity, but also include changes in soft palate, pharynx and upper third of the oesophagus and often leads to difficulty in Swallowing, difficulty in opening mouth due to loss of cheek flexibility.

The soft palate is the fibrous and vascular tissue which is attached to posterior border of hard palate and the morphological shapes of soft palate is varied depending on habit, age and gender of subjects.<sup>2</sup>

The Digital lateral cephalogram view is by far the most valuable view for evaluation of soft palate as Numerous authors stated that with increasing age changes in dimension of velum seen in patients not only with OSMF but in sleep apnea, cleft lip and palate also. The DLC is a helpful tool to analyse the Patterns of velar in OSMF with different age groups, and gender. Hence, the need for the present study was felt for early detection of disease and to assess the changes in the soft palate morphology that can be helpful in treatment OSA and Cleft palate.

### **Material and Methodology**

The study was conducted in the Department of OMR at TMDCRC, Moradabad. This study comprised of 100 patients, of both genders within the age group of 18- 45 years. These Subjects were further divided into two groups of 50 Patients each. In Group I (study group) Clinically diagnosed with OSMF as and Group II individuals having history of habit with no mucosal changes which were further evaluated radiographically to rule out any changes in soft palate. Permission to perform the study was obtained from ethical committee of TMDCRC, Moradabad, Uttar Pradesh. Every patient selected was informed about the study and Informed consent were procured from them.

Written informed consent was obtained from all the patients after explaining the study and treatment protocols. Detailed case history was recorded with particular emphasis on type, frequency per day, and duration of adverse habits (areca nut, gutka, or a combination of both). Based on the clinical findings, the final diagnosis of OSMF is given based on the criteria given by Ranganathan et al (2001).

As per the covid instruction and a proper clinical examination were carried out in department. The clinical examination of selected patient were diagnosed with OSMF as per the criteria given by Ranganathan et al (2001) he has classified the various categories according to sign and symptoms as

- Class 1- only symptoms, with no demonstrable restriction of mouth opening.
- Class 2- limited mouth opening 20 mm and above.
- Class 3-mouth opening less than 20 mm.
- Class 4-OSMF advanced with limited mouth opening. Precancerous changes seen throughout the mucosa.

Later these subjects were evaluated for radiographic examination at Dept. of OMR for Digital lateral Cephalograms. These digital images were transferred into computer system and then analysed for the morphology of soft palate according to criteria given by You et al (2008)<sup>3</sup> and Rathore et al (2019)<sup>4</sup>.

According to the criteria given by You et al there are six shapes i.e.,

Type 1- leaf shape (Fig.1)

Type 2-rat tail, (Fig.2)

Type 3-butt shape, (Fig.3)

Type 4-straight line shape, (Fig.4)

Type 5-s shape, (Fig.5)

Type 6-crook shape, (Fig.6)

Supriya Rathore et al as given another two new shapes.

Type 7-u shape, (Fig.7)

Type 8 -bifid shape. (Fig.8)

Later the morphometric evaluation is done by Master edit PDF 5.7 version Software. The measurement of SP such as length and SI and AP dimension were evaluated from PNS to tip of uvula similarly greatest width was SI diameter of the soft palate.

The data was entered in the Microsoft Excel 2007 & using the SPSS statistical software 23.0 Version it was determined. The difference of mean scores between two independent groups was done using the unpaired/independent t test. The intergroup comparison for the frequencies was done using the Chi square test. The level of the significance for the present study was fixed at 5%.

#### **Inclusion Criteria**

- Patients clinically diagnosed with oral submucous fibrosis (OSMF) and individual with the history of habit without any mucosal changes were informed about the study protocol and selection were based on their willingness to take part in the study.

#### **Exclusion Criteria**

- Congenital anomalies i.e. congenital cleft lip and palate, systemic disease, syndrome. Surgery of Oro pharyngeal region and trauma to head and neck and region any Odontogenic or space infections Pregnant and lactating females.

#### **Results and observation**

Intergroup variation of soft palate shapes with different stages in osmf group were In Stage I About 7 (43.8%) Type 1 (Leaf) shape, Similarly in Stage II more no. of patterns found in Type 2 (Rat tail) shape about 7 (38.9%) However, in stage III OSMF the more no. of shapes found in Type 3 (Butt) 5(41.7) Similarly in Stage IV only Type 1 (Leaf) and Type 2 (Rat tail) pattern were found in 2 subject each 2 shape (0.2%) and none of the

shape found in Straight line, Crook, U shape and Triangular, Beak. shape P value 0.001 which is statistically significant. (Table 1)

Age related changes in shapes of soft palate in control group 16-25 year (Rat tail) (38.5%),26-35 year (S Shape) 2 (33.3%),36-45 year (Rat tail) (40.0%) similarly in study group 16-35 Year (leaf shape) 11 (34.4%),26-35 year (leaf shape) 4 (40.0%),36-45 Year (leaf shape) (37.5%) were commonly noticed.

In control group Type 2 (Rat Tail) shape was predominant in both males and female's subjects. Similarly in study group Type 1 (leaf shape) was more common in both males and female's subjects.

Intergroup difference in the morphology of velar in Control group the predominantly Type 2 (Rat shape) 18 (36.0%), Similarly in Study group was found that predominantly more number of (leaf) shape Type 1 of S.P18(36.0%) were found with P value of 0.001 which is statistically significant. (Table 2)

The Anteroposterior parameter of between both and control and study group with the mean score 28.87 with Std. Deviation 3.187 in control group and it was found that mean 26.96 and Std. Deviation 5.083 in study group which is statistically significant with P Value of 0.027.(Table 3)

The Intergroup comparison of SI parameter between the both Control and study group was 7.98 with Std. Deviation 1.433 in control group and in study group with mean value of 7.96 With Std. Deviation 1.272 which is statistically significant with P value of 0.937.(Table 4)

## Discussion

Lateral cephalogram is one of the acceptable techniques to evaluate morphological and morphometric changes in soft palate. The morphological pattern of velar as being one to ignore in the past but it has variable presentation on lateral cephalogram as it is based on slit radiography

so the acquired image formed can be enhanced, easy to extract measurement.

In the present study ,comparison of shape between different stages in group 1 (OSMF) shows predominantly 7 (43.8%) Type 1(leaf) shape in stage I,7 ( 38.9%) Type 2 (rat tail) in stage II ,5 (41.7%) Type 3 (Butt) shape in stage III and 2 cases (50.0%) in each Type 1& Type 2 (Rat tail) shape in stage IV were noticed ,While in stage I Butt and straight line 1(6.2%), Type 5 (S shape), Type 10 (Beak) shape 1(5.6%) each in stage II, Type 2 (Rat tail) , Type 5 (S shape), Type 10 (Triangular) 1(8.3%) in Stage III, None of the cases reported in Stage IV other than Type 1(leaf) and Type 2 (Rat tail) were noticed as least shape in our study which is in accordance to the study done by Shanker VN et al (2013)<sup>5</sup>, Lakshmi C et al (2015)<sup>2</sup> except the triangular and beak shape.

A Study done by Upadhyay C et al (2017)<sup>6</sup>, Alok A et al (2019)<sup>7</sup> have noticed the same results other than the two new shapes in present study as in Control Group, soft palate Morphology commonly seen in age group of 16-25 year is Type 2 (Rat tail) of about 15(38.5%) and least shape found to be Type 4,5,6,7,8,9,10 1(2.6%) each. In 26-35 Type 5(S shape) 2(33.3%) are commonly found, and least number of shapes was observed are Leaf and Rat tail, Butt Shape, crook shape 1 (16.7%) similarly in 36-45 age group Type 2 (Rat tail) shapes of soft palate of about 2(40.0%) is commonly seen, while in 36-45 age group type 1 (Leaf), Type 3 (Butt Shape), Type 9 (Triangular) 1(40.0%) were found.

In group 1 (Study) age related changes in soft palate morphology found that Type 1 (leaf) of about (34.4%) in age group 16–25-year, and in 26-35 year &36-45 year of age about (40.0%) and (37.5%) leaf shape which is according to the study done by Rathore et al (2019)<sup>4</sup>. However, in control group the similar gender related

changes were observed predominantly Type 2 (Rat tail) shapes of about 9(40.9%) compare to all other shapes and in males it was found that more number of shapes seen in (leaf shape) Type 1 and (Rat tail) of about 9(32.1%) with P value of 0.001 statistically significant, which is similar to the study done by Khaitan T et al (2016)<sup>8</sup>, Nagaraj T et al (2016)<sup>9</sup>.

However, gender related changes of soft palate also found more predominance in Type 1 of about 11(44.0%) in females followed by Type 2 shape of soft palate of about 7(28.0%) and in males it shows more in Leaf shape of about 7(28.0%) respectively, It is parallel to study done by Lakshmi C et al, (2016)<sup>2</sup>, Tripathy et al (2020)<sup>10</sup>.

The shapes of soft palate compare with the two groups such as Group I and Group II. In group I (Study) predominantly leaf shape were higher in number of about 18(36%) and least number of shapes found in Straight line, U shape, Bifid, Beak shape similarly in Group II (control) it was found predominantly Type 1 i.e.,18(36%) and least no. of shapes of pattern Type 4, Type 9 and Type 10 seen respectively. Similarly, study done by Tripathy et al (2020)<sup>10</sup>, Domir S K et al (2019)<sup>11</sup>.

The Anteroposterior dimension were compared with both control and study Group. In group 1 (study) with mean score 29.96 with Std. Deviation 5.083 and similarly in control group mean score was about 28.87 with Std. Deviation 3.187 which is statistically significant 0.027, which is similar to Shanker VN (2013)<sup>5</sup> and Rathore et al (2019)<sup>4</sup>.

The Super inferior parameter observed between the groups. It was found that in Group I (study) the mean score of 7.96 with Std. Deviation 1.272 in Group II (control) showed the mean score of 7.98 with Std. Deviation 1.433 respectively with P value of 0.937

which is statistically non-significant, similar to study done by Shanker VN et al<sup>5</sup>. However, Triangular and beak shape are the two new shapes not to be found in any of the study.

### Conclusion

In addition to Eight shapes, another two new shapes such as Triangular shape(fig.9) and beak shape (fig.10) were found in the study through Digital Lateral Cephalogram. These two Shapes are unique and not mentioned in any of the available literature.

The A-P dimension of soft palate was seen to be reducing as the disease progresses.

Hence the study can be helpful in early detection of changes in soft palate that could be helpful in the treatment of OSMF and can be beneficial in the management of OSA and cleft palate.
